ALGO

- Start: Create a new Java project in Eclipse to start the automation process. Set up the WebDriver in the STS project properties to allow for easy web application interaction.

- Write scripts for Selenium:
  Create two Java classes with the necessary Selenium WebDriver commands: RegistrationTest.java and LoginTest.java. By interacting with web elements on the corresponding pages, these scripts will manage the registration and login functionalities.

- Examine and verify:
  Examine the code carefully to find and fix any mistakes or places that could use better. To make sure the automation scripts correctly complete the web application's registration and login processes, test them locally.

- End: Declare that the automation process has been completed and that all required actions—from project inception to testing and documentation—have been carried out satisfactorily.
